

training stress depends not only on the magnitude of the stress, but also on how the athlete encounters it. We could express this idea with a simple equation:

Adaptation = Training Stress × Involvement

If the athlete's involvement approaches zero, even exceptional training produces inadequate adaptation. The sessions are completed, but the internal response becomes dreary.

Athletes feel this long before it appears in performance metrics.

When discipline becomes an enclosure

Discipline is essential in endurance sports, but it has a dim side too. When discipline loses its connection with purpose, it can quietly turn into

a dicey enclosure.

The athlete becomes extremely good at following a system, but the system slowly replaces the experience of feeling alive and engaged.

You can recognise these athletes easily:

- They rarely miss sessions.
- They rarely deviate from plans.
- They rarely take risks in races.
- They also rarely surprise themselves.

They have mastered execution, but lost exploration, curiosity and enjoyment. It becomes a pedantic way of ticking boxes under the pretext of discipline and dedication. When there is no enjoyment in sessions, and no sense of looking forward to experimenting or doing something different (not always, but

Time to look within: When there is no enjoyment in sessions, and no sense of looking forward to experimenting or doing something different, performance stagnates. GETTYIMAGES

at times), performance stagnates.

Endurance sports, despite their structure, remain deeply exploratory.

Game is not a controlled experiment

Training environments are controlled. Game environments, with so many variables, cannot be replicated in any controlled setting. To be ready and prepared for variability is what transforms a normal player into an iconic one.

Adaptation is king in that moment.
