NBA scouts and coaches tout the advantages of having a long reach or wingspan. In 2012, the average height of an NBA player was about 6'7" with an average wingspan of around seven feet. In what ways is a long wingspan an advantage in tennis?

There are four important ways.

First, a longer wingspan increases court coverage. It allows a player to reach more balls, making it easier to return shots that would be out of reach for players with shorter arms. This is especially useful in defence and when stretching for wide shots when returning serve and during baseline rallies.

Second, it helps you play better at the net. A longer reach aids in volleys and overheads, allowing a player to cover more area and put away shots more effectively. Players like 6'10" John Isner and 6'6" Daniil Medvedev use their reach well at the net.

Third, it enhances both the quality and consistency of serves. A long wingspan contributes to a higher contact point on serves, generating more leverage and power. This can help in hitting a more effective kick serves and achieving greater angles.

Fourth, it provides greater ball-striking leverage. A longer arm span can create more torque on groundstrokes, increasing shot power and spin potential.

However, longer wingspans have potential downsides. First, they generally result in a slower swing speed on groundstrokes. A longer lever arm requires more control and strength, which can make quick adjustments harder.

Second, players with a longer wingspan typically have less
