

How To Write Class-Based Views with Generic Views

```
views.py
from django.views.generic import ListView
from .models import MyModel

class MyView(ListView):

    template_name = 'list.html'
    model = MyModel

    def get_context_data(self, **kwargs):
        context = super().get_context_data(**kwargs)
        context['now'] = timezone.now()
        return context
```

- 1 Import generic views and models used in this view
- 2 Create a new view using a generic view
- 3 Set 'attribute values' for each attribute defined for each generic view
- 4 Customize the generic view (e.g., set a new context)

Django generic views are designed using **Python classes**. How to use generic views in *views.py* follows the **Python class syntax**. Basically, you'll need to create a new view as a child class of a built-in generic view. The new view inherits the attributes and methods from the built-in generic view. When you make a new view using a generic view, the code has four sections.

1. **Import generic views and models** used in this view
2. **Create a new view** using a generic view
3. **Set 'attribute values'** for each attribute defined for each generic view
