

- `template_name`: set an html file used for this view
- `model`: set a model to be used for this view

4 Customize the generic view

Although generic views are equipped with basic functionalities, you may need to customize them. For example, you can do the following things by customizing generic views.

- add a query to show selected data or to change the order of content items
- add context (a dictionary of data that is passed from a view to an HTML template)
- add logic to display content such as differentiating user interface depending on login status

Customization of views is done in a way that overrides the method defined in the generic view. In the main figure example, `get_context_data` is a method to get the **context data** of the model. The `get_context_data` method is accessible from *ListView*, but it is initially defined in the *SingleObjectMixin* class. *ListView* inherits the method from the *SingleObjectMixin* class.

We'll explain the **context** and how to override a method later in this chapter.
