

`pk` means **primary key**, which is set in the auto-generated id field by default. `<int:pk>` is just an example. You can set other types of path converters using the `<data type:name>` format. The data type examples are:

- `str` - Matches any non-empty string
- `slug` - Matches any slug string consisting of ASCII letters or numbers, plus the hyphen and underscore characters

3. Edit the project `urls.py` file

Creating and editing the `urls.py` file under the app directory is not enough to complete the URL dispatcher. You need to link the newly created `urls.py` file with the project `urls.py` file by adding the `include` function, as in the example below.

```
from django.urls import path, include
:
urlpatterns = [
    path('app-name/', include('app_name.urls')),
]
```

Practice

In this practice, we'll create a URL dispatcher for the views designed in the previous practice.

1. Create a new `urls.py` file under the `employee_learning` directory

The `urls.py` file is not generated by the `startapp` command. You need to create a new `urls.py` file under the `employee_learning` directory.

Command Line - INPUT
