

users/admin.py

```
from django.contrib import admin
from .models import UserProfile
admin.site.register(UserProfile)
```

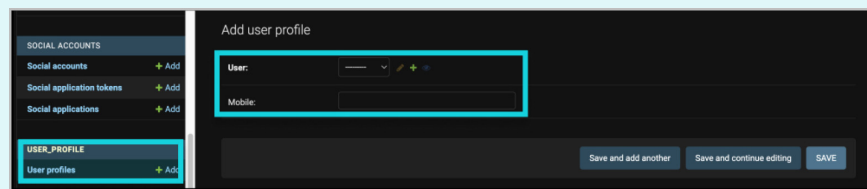

5. Check the results

Run the `makemigrations` and `migrate` commands as we have created a new model. To see the outcome, execute the `runserver` command.

Command Line - INPUT

```
d_env) project_d % | python manage.py makemigrations user_profile
d_env) project_d % | python manage.py migrate
d_env) project_d % | python manage.py runserver
```

Go to localhost:8000/admin. You can see that the `UserProfile` model is registered under the new app. Using the same approach, you can extend the user model further.

Substituting the user model – Creating a custom model using AbstractUser

If you want to have a more customized user model with specific fields, you need to build a custom model inheriting the built-in user model.

AbstractUser vs. AbstractBaseUser

There are two built-in user models that you can utilize – *AbstractUser* and *AbstractBaseUser*.
