

Manage Local Computer and Remote Server Simultaneously

Now you can access the server (**Ubuntu Instance**) remotely using **VS Code** and terminal. This means you are managing two machines on your local computer. One is your local computer itself, and the other is the remote server.

In the app deployment process, you need to be clear about which computer you are handling.

You can open two VS Code windows with a terminal inside to manage the two computer resources. You can check which computer resources (remote vs. local) you are accessing from the two points.
