

The screenshot shows the AWS Lightsail console interface for a domain named **example.com**. At the top, there is a logo with three orange circles and the text "example.com", "DNS zone", and "Global, all zones". Below this, there are three tabs: "Domains" (which is selected and underlined), "Assignments", and "DNS records". A red vertical ellipsis menu icon is located to the right of the tabs.

Under the "Domains" tab, the section is titled "Domain". Below the title, it says "Use this DNS zone to manage your domain." There is a green information icon (i) in a circle, followed by the text: "Update the name servers of your domain to match the name servers of this DNS zone."

Below this, the section is titled "Name servers". The text explains: "Lightsail assigns name servers when you create a DNS zone. To make Lightsail the DNS service for a domain, you configure the domain registration to use these name servers. [Learn more about name server records](#)".

A list of four name servers is shown, each preceded by "ns-":

- ns- .awsdns-52.org
- ns- .awsdns-03.net
- ns- .awsdns-00.co.uk
- ns- .awsdns-14.com

This list is enclosed in an orange rectangular box.

Assign the domain to the static IP address in the Lightsail console

To match your domain name and static IP address, assign the domain to the static IP address. This action is the same as adding an **A record** to the DNS.

For the domain, you can also use a **subdomain**.
