

**Table C.3** Built-in Django template filters (*continued*)

| Filter                                                                           | Description                                                                                                                                                                                                                                                                      |
|----------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <pre>{{ value pluralize }}</pre> <p>or</p> <pre>{{ value pluralize:"es" }}</pre> | This returns <code>s</code> if <code>value</code> is 2 or greater. Given an argument, it returns the argument instead of <code>s</code> . The second example returns "es" if <code>value</code> is greater than 1.                                                               |
| <pre>{{ value pprint }}</pre>                                                    | This is a wrapper around Python's <code>pprint.pprint()</code> function, which is useful when debugging.                                                                                                                                                                         |
| <pre>{{ value random }}</pre>                                                    | This returns a random item from a list.                                                                                                                                                                                                                                          |
| <pre>{{ value rjust:"15" }}</pre>                                                | This adds whitespace to right justify the contents for the given width. Note: this is only visible in HTML inside certain tags, as HTML normally ignores whitespace.                                                                                                             |
| <pre>{{ value safe }}</pre>                                                      | This marks a string as not requiring HTML escaping. It has no effect if auto-escaping is turned off.                                                                                                                                                                             |
| <pre>{{ value safeseq }}</pre>                                                   | This applies the <code> safe</code> filter to each item in a list.                                                                                                                                                                                                               |
| <pre>{{ value slice:".2" }}</pre>                                                | This performs Python list slicing.                                                                                                                                                                                                                                               |
| <pre>{{ value slugify }}</pre>                                                   | This converts <code>value</code> into a newspaper slug. It removes any character that isn't an alphanumeric, underscore, or hyphen; converts it to lowercase; and removes any leading or trailing whitespace.                                                                    |
| <pre>{{ value stringformat:"E" }}</pre>                                          | This performs printf-style string formatting on <code>value</code> . Note the argument does not use the percent symbol. For example, the argument <code>"03d"</code> is the equivalent of the format string <code>%03d</code> .                                                  |
| <pre>{{ value striptags }}</pre>                                                 | This attempts to strip XML or HTML tags from a string. Note that there are tricky things users can do to get around this; do not assume the result of this filter can be marked as safe. If you absolutely must allow user input HTML, use a third-party HTML sanitizer library. |
| <pre>{{ value time:"H:i" }}</pre>                                                | This converts a time object to a string, using the argument as a string formatter. See the <code> date</code> filter.                                                                                                                                                            |
| <pre>{{ value timesince:comparison }}</pre>                                      | This returns the amount of time that has expired between <code>value</code> and <code>comparison</code> , in human-readable format (5 days, 3 hours).                                                                                                                            |
| <pre>{{ value timeuntil:comparison }}</pre>                                      | This returns the amount of time remaining between <code>value</code> and <code>comparison</code> , in human-readable format.                                                                                                                                                     |
| <pre>{{ value title }}</pre>                                                     | This converts a string to title case.                                                                                                                                                                                                                                            |
| <pre>{{ value truncatechars:7 }}</pre>                                           | This truncates a string to the given number of characters. Truncated strings end with an ellipsis (...).                                                                                                                                                                         |
| <pre>{{ value truncatechars_html:7 }}</pre>                                      | This is an HTML-aware version of <code> truncatechars</code> .                                                                                                                                                                                                                   |
| <pre>{{ value truncatewords:7 }}</pre>                                           | This is like <code> truncatechars</code> but counts the number of words instead of the number of characters.                                                                                                                                                                     |
| <pre>{{ value truncatewords_html:7 }}</pre>                                      | This is an HTML-aware version of <code> truncatewords</code> .                                                                                                                                                                                                                   |
