

appendix D

Django ORM field reference

This appendix is a reference guide for Django’s built-in Database ORM fields. For a full reference, see the online documentation: <https://docs.djangoproject.com/en/dev/ref/models/fields/>.

D.1 Field options

Table D.1 contains the constructor arguments that can be used in all ORM field types.

Table D.1 Arguments common to all fields

Argument	Description
<code>null</code>	When <code>True</code> , empty values are stored in the database as <code>NULL</code> .
<code>blank</code>	When <code>True</code> , the value is allowed to be blank. Note: this is different from <code>null</code> , which is related to database storage. This field is used during field validation—for example, in the Django Admin.
<code>choices=[("en", "English"), ("fr", "French")]</code>	If present, this argument restricts the values allowed. The restriction is applied during the Model’s validation step. The argument takes a sequence of tuples, with the first item in each tuple being what is stored in the database (<code>"en"</code> or <code>"fr"</code>) and the second item in each tuple being the value displayed to the user (<code>"English"</code> or <code>"French"</code>) in forms, including the Django Admin.
<code>db_column</code>	This is used to force the name of the database column; when it is not given, Django bases the column name on the field’s name.
