

If your comment spans multiple lines, it's better to use a single multiline comment than several consecutive single-line comments, which are harder to read, as you can see here:

```
"""This is a good way
to write a comment
that spans multiple lines. """
# This is not a good way
# to write a comment
# that spans multiple lines.
```

Comments and documentation are often afterthoughts in the programming process or are even considered by some to do more harm than good. But as “Myth: Comments Are Unnecessary” on page 83 explained, comments are not optional if you want to write professional, readable code. In this section, we’ll write useful comments that inform the reader without detracting from the program’s readability.

Comment Style

Let’s look at some comments that follow good style practices:

```
❶ # Here is a comment about this code:
    someCode()

❷ # Here is a lengthier block comment that spans multiple lines using
    # several single-line comments in a row.
❸ #
    # These are known as block comments.

if someCondition:
    ❹ # Here is a comment about some other code:
    ❺ someOtherCode() # Here is an inline comment.
```

Comments should generally exist on their own line rather than at the end of a line of code. Most of the time, they should be complete sentences with appropriate capitalization and punctuation rather than phrases or single words ❶. The exception is that comments should obey the same line-length limits that the source code does. Comments that span multiple lines ❷ can use multiple single-line comments in a row, known as *block comments*. We
