

end of the Python script to prevent the program's window from disappearing too quickly.

I recommend you place all of your batch and `.py` files in a single folder that already exists in the `PATH` environment variable, such as your home folder at `C:\Users\<USERNAME>`. With a batch file set up, you can run your Python script by simply pressing WIN-R, entering the name of your batch file (entering the `.bat` file extension is optional), and pressing ENTER.

Running Python Programs on macOS

On macOS, you can create a shell script to run your Python scripts by creating a text file with the `.command` file extension. Make one in a text editor, such as TextEdit, and add the following content:

```
#!/usr/bin/env bash
python3 /path/to/yourScript.py
```

Save this file in your home folder. In a terminal window, make this shell script executable by running `chmod u+x yourScript.command`. Now you should be able to click the Spotlight icon (or press COMMAND-SPACE) and enter the name of your shell script to run it. The shell script, in turn, will run your Python script.

Running Python Programs on Ubuntu Linux

There isn't a quick way to run your Python scripts on Ubuntu Linux like there is in Windows and macOS, although you can shorten some of the steps involved. First, make sure your `.py` file is in your home folder. Second, add this line as the first line of your `.py` file:

```
#!/usr/bin/env python3
```

This is called a *shebang line*, and it tells Ubuntu that when you run this file, you want to use `python3` to run it. Third, add the execute permission to this file by running the `chmod` command from the terminal:

```
al@al-VirtualBox:~$ chmod u+x yourScript.py
```
