

Now whenever you want to quickly run your Python script, you can press CTRL-ALT-T to open a new terminal window. This terminal will be set to the home folder, so you can simply enter `./yourScript.py` to run this script. The `./` is required because it tells Ubuntu that *yourScript.py* exists in the cwd (the home folder, in this case).

Summary

Environment setup involves all the steps necessary to get your computer into a state where you can easily run your programs. It requires you to know several low-level concepts about how your computer works, such as the filesystem, file paths, processes, the command line, and environment variables.

The filesystem is how your computer organizes all the files on your computer. A file is a complete, absolute file path or a file path relative to the cwd. You'll navigate the filesystem through the command line. The command line has several other names, such as terminal, shell, and console, but they all refer to the same thing: the text-based program that lets you enter commands. Although the command line and the names of common commands are slightly different between Windows and macOS/Linux, they effectively perform the same tasks.

When you enter a command or program name, the command line checks the folders listed in the `PATH` environment variable for the name. This is important to understand to figure out any `command not found` errors you might encounter. The steps for adding new folders to the `PATH` environment variable are also slightly different between Windows and macOS/Linux.

Becoming comfortable with the command line takes time because there are so many commands and command line arguments to learn. Don't worry if you spend a lot of time searching for help online; this is what experienced software developers do every day.
