

In both cases, the code uses the + operator to add three values, but without spacing, the + in `blanks[i+1:]` can appear to be adding a fourth value. The spaces make it more obvious that this + is part of a slice for the value in `blanks`.

Put No Spaces Before Separators and a Single Space After Separators

We separate the items lists and dictionaries, as well as the parameters in function `def` statements, using comma characters. You should place no spaces before these commas and a single space after them, as in this example:

```
YES: def spam(eggs, bacon, ham):  
YES:     weights = [42.0, 3.1415, 2.718]
```

Otherwise, you'll end up with “bunched up” code that is harder to read:

```
NO:  def spam(eggs,bacon,ham):  
NO:      weights = [42.0,3.1415,2.718]
```

Don't add spaces before the separator, because that unnecessarily draws the eye to the separator character:

```
NO:  def spam(eggs , bacon , ham):  
NO:      weights = [42.0 , 3.1415 , 2.718]
```

Black automatically inserts a space after commas and removes spaces before them.

Don't Put Spaces Before or After Periods

Python allows you to insert spaces before and after the periods marking the beginning of a Python attribute, but you should avoid doing so. By not placing spaces there, you emphasize the connection between the object and its attribute, as in this example:

```
YES: 'Hello, world'.upper()
```
