

If you put spaces before or after the period, the object and attribute look like they're unrelated to each other:

NO: `'Hello, world' . upper()`

Black automatically removes spaces surrounding periods.

Don't Put Spaces After a Function, Method, or Container Name

We can readily identify function and method names because they're followed by a set of parentheses, so don't put a space between the name and the opening parenthesis. We would normally write a function call like this:

YES: `print('Hello, world!')`

But adding a space makes this singular function call look like it's two separate things:

NO: `print ('Hello, world!')`

Black removes any spaces between a function or method name and its opening parenthesis.

Similarly, don't put spaces before the opening square bracket for an index, slice, or key. We normally access items inside a container type (such as a list, dictionary, or tuple) without adding spaces between the variable name and opening square bracket, like this:

YES: `spam[2]`

YES: `spam[0:3]`

YES: `pet['name']`

Adding a space once again makes the code look like two separate things:

NO: `spam [2]`

NO: `spam [0:3]`

NO: `pet ['name']`
