

Black removes any spaces between the variable name and opening square bracket.

Don't Put Spaces After Opening Brackets or Before Closing Brackets

There should be no spaces separating parentheses, square brackets, or braces and their contents. For example, the parameters in a `def` statement or values in a list should start and end immediately after and before their parentheses and square brackets:

```
YES: def spam(eggs, bacon, ham):  
YES:     weights = [42.0, 3.1415, 2.718]
```

You should not put a space after an opening or before a closing parentheses or square brackets:

```
NO:  def spam( eggs, bacon, ham ):  
NO:      weights = [ 42.0, 3.1415, 2.718 ]
```

Adding these spaces doesn't improve the code's readability, so it's unnecessary. Black removes these spaces if they exist in your code.

Put Two Spaces Before End-of-Line Comments

If you add comments to the end of a code line, put two spaces after the end of the code and before the `#` character that begins the comment:

```
YES: print('Hello, world!') # Display a greeting.
```

The two spaces make it easier to distinguish the code from the comment. A single space, or worse, no space, makes it more difficult to notice this separation:

```
NO:  print('Hello, world!') # Display a greeting.  
NO:  print('Hello, world!')# Display a greeting.
```

Black puts two spaces between the end of the code and the start of the comment.
