

address. If you felt that this task was really composed of multiple subtasks, you could insert blank lines to separate them.

The programmer for this part of Django decided that the domain validation lines should all belong to one group, but other programmers might disagree. Because it's subjective, Black won't modify the vertical spacing within functions or methods.

Vertical Spacing Best Practices

One of Python's lesser-known features is that you can use a semicolon to separate multiple statements on a single line. This means that the following two lines:

```
print('What is your name?')
name = input()
```

... can be written on the same line if separated by a semicolon:

```
print('What is your name?'); name = input()
```

As you do when using commas, you should put no space before the semicolon and one space after it.

For statements that end with a colon, such as `if`, `while`, `for`, `def`, or `class` statements, a single-line block, like the call to `print()` in this example:

```
if name == 'Alice':
    print('Hello, Alice!')
```

... can be written on the same line as its `if` statement:

```
if name == 'Alice': print('Hello, Alice!')
```

But just because Python allows you to include multiple statements on the same line doesn't make it a good practice. It results in overly wide lines of code and too much content to read on a single line. Black splits these statements into separate lines.
