

term *localhost* refers to a server that only processes requests on your system; it doesn't allow anyone else to see the pages you're developing.

Open a web browser and enter the URL `http://localhost:8000/`, or `http://127.0.0.1:8000/` if the first one doesn't work. You should see something like Figure 18-1: a page that Django creates to let you know everything is working properly so far. Keep the server running for now, but when you want to stop the server, press CTRL-C in the terminal where the `runserver` command was issued.

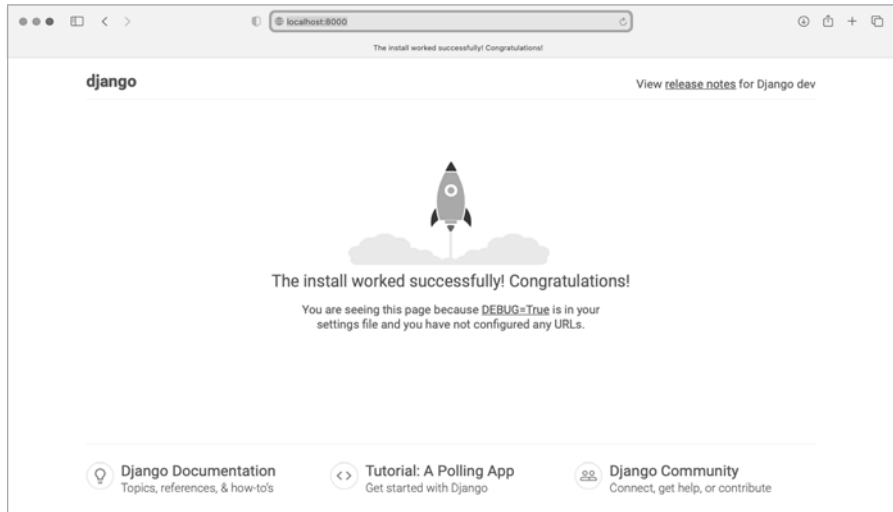

Figure 18-1: Everything is working so far.

NOTE

If you receive the error message “That port is already in use,” tell Django to use a different port by entering `python manage.py runserver 8001` and then cycling through higher numbers until you find an open port.

TRY IT YOURSELF

18-1. New Projects: To get a better idea of what Django does, build a couple empty projects and look at what Django creates. Make a new folder with a simple name, like `tik_gram` or `insta_tok` (outside of your `learning_log` directory), navigate to that folder in a terminal, and create a virtual environment. Install Django and run the command `django-admin.py startproject tg_project .` (making sure to include the dot at the end of the command).

Look at the files and folders this command creates, and compare them to Learning Log. Do this a few times, until you're familiar with what Django creates when starting a new project. Then delete the project directories if you wish.
