

The login page's pattern matches the URL *http://localhost:8000/accounts/login/*. When Django reads this URL, the word *accounts* tells Django to look in *accounts/urls.py*, and *login* tells it to send requests to Django's default login view.

The login Template

When the user requests the login page, Django will use a default view function, but we still need to provide a template for the page. The default authentication views look for templates inside a folder called *registration*, so we'll need to make that folder. Inside the *ll_project/accounts/* directory, make a directory called *templates*; inside that, make another directory called *registration*. Here's the *login.html* template, which should be saved in *ll_project/accounts/templates/registration/*:

```
login.html  {% extends 'learning_logs/base.html' %}

            {% block content %}

❶      {% if form.errors %}
            <p>Your username and password didn't match. Please try again.</p>
            {% endif %}

❷      <form action="{% url 'accounts:login' %}" method='post'>
            {% csrf_token %}
❸      {{ form.as_div }}

❹      <button name="submit">Log in</button>
            </form>

            {% endblock content %}
```

This template extends *base.html* to ensure that the login page will have the same look and feel as the rest of the site. Note that a template in one app can inherit from a template in another app.

If the form's `errors` attribute is set, we display an error message ❶, reporting that the username and password combination doesn't match anything stored in the database.

We want the login view to process the form, so we set the `action` argument as the URL of the login page ❷. The login view sends a `form` object to the template, and it's up to us to display the form ❸ and add a submit button ❹.

The LOGIN_REDIRECT_URL Setting

Once a user logs in successfully, Django needs to know where to send that user. We control this in the settings file.
