

You'll need to install two more packages to make the most of your Python installation:

```
$ sudo apt install python3.11-dev python3.11-venv
```

These packages include modules you'll need when installing and running third-party packages, like the ones used in the projects in the second half of the book.

NOTE

The `deadsnakes` package has been actively maintained for a long time. When newer versions of Python come out, you can use these same commands, replacing `python3.11` with the latest version currently available.

Checking Which Version of Python You're Using

If you're having any issues running Python or installing additional packages, it can be helpful to know exactly which version of Python you're using. You may have multiple versions of Python installed and not be clear about which version is currently being used.

Issue the following command in a terminal:

```
$ python --version
Python 3.11.0
```

This tells you exactly which version the command `python` is currently pointing to. The shorter command `python -V` will give the same output.

Python Keywords and Built-in Functions

Python comes with its own set of keywords and built-in functions. It's important to be aware of these when you're naming things in Python: your names cannot be the same as these keywords and shouldn't be the same as the function names, or you'll overwrite the functions.

In this section, we'll list Python's keywords and built-in function names, so you'll know which names to avoid.

Python Keywords

Each of the following keywords has a specific meaning, and you'll see an error if you try to use any of them as a variable name.

False	await	else	import	pass
None	break	except	in	raise
True	class	finally	is	return
and	continue	for	lambda	try
as	def	from	nonlocal	while
assert	del	global	not	with
async	elif	if	or	yield
