

Here's a test for the `area_rect()` function from Card 6.8:

```
import unittest
import area_functions as af

class AFTestCase(unittest.TestCase):
    """Tests for area_functions.py."""

    def test_rect_area(self):
        """Test a simple rectangle."""
        area = af.area_rect(3, 4)
        self.assertEqual(area, 12)

if __name__ == '__main__':
    unittest.main()
```

You import `unittest` and the module you're testing. Test class names usually end in `TestCase`; a prefix indicates what they test. The test class must be a child class of `unittest.TestCase`.

Each test is a method. Every method that starts with `test_` runs when the tests run. The method `test_area_rect()` calls `area_rect()` with the rectangle dimensions and then tests for the correct area.
