

In Python 3.6 onward, you can use a variable directly inside a string:

```
>>> username = 'efermi'
>>> print(f"Welcome back, {username}!")
Welcome back, efermi!
```

The *f* is short for *format* and tells Python to insert the value of the variable listed in braces inside the string. This tells Python to format the string using the given variable's value.

In Python 3.5 and earlier, you must use the `format()` method:

```
>>> username = 'efermi'
>>> msg = "Welcome back, {}".format(username)
>>> print(msg)
Welcome back, efermi!
```

The placeholder `{}` will be replaced by the first variable included in the call to `format()`. You can include as many variables as you need:

```
>>> msg = "Welcome, {} and {}".format(
    username_0, username_1)
```
