

```
        matchedFiles.extend(walk(filepath, matchFunc))
    return matchedFiles

print('All files with even byte sizes:')
print(walk('.', hasEvenByteSize))
print('All files with every vowel in their name:')
print(walk('.', hasEveryVowel))
```

The file-search program’s main function is `walk()`, which “walks” across the entire span of files in a base folder and its subfolders. It calls one of two other functions that implement the custom search criteria it’s looking for. In the context of this program, we’ll call these *match functions*. A match function call returns `True` if the file matches the search criteria; otherwise, it returns `False`.

The job of the `walk()` function is to call the match function once for each file in the folders it walks across. Let’s take a look at the code in more detail.
