
```
def hasEveryVowel(fullFilePath):  
    """Returns True if the fullFilePath has a, e, i, o, and u,  
    otherwise returns False."""  
    name = os.path.basename(fullFilePath).lower()  
    return ('a' in name) and ('e' in name) and ('i' in name) and ('o' in name) and ('u' in name)
```

We call `os.path.basename()` to remove the folder names from the filepath. Python does case-sensitive string comparisons, which ensures that `hasEveryVowel()` doesn't miss any vowels in the filename because they are uppercase. For example, calling

`os.path.basename('C:/Windows/system32/notepad.exe')` returns the string `notepad.exe`. This string's `lower()` method call returns a lowercase form of the string so that we have to check for only lowercase vowels in it. “Useful Python Standard Library Functions for Working with Files” later in this chapter explores some more functions for finding out information about files.

We use a `return` statement with a lengthy expression that evaluates to `True` if `name` contains `a`, `e`, `i`, `o`, or `u`, indicating the file matches the search criteria. Otherwise, the `return` statement returns `False`.
