

loop repeats this four times to create the square. When the function finally calls `turtle.end_fill()`, the filled-in square appears on the screen.

The drawTriangleOutline() Function

The second shape-drawing function draws the outline of an equilateral triangle whose sides have a length of `size`. The function draws the triangle oriented with one corner at the top and two corners at the bottom. [Figure 13-6](#) illustrates the various dimensions of an equilateral triangle.

Figure 13-6: The measurements of an equilateral triangle with sides the length of `size`

Before we begin drawing, we must determine the triangle's height based on the length of its sides. Geometry tells us that, for equilateral triangles with sides of length L , the height h of the triangle is L times the square root of 3 divided by 2. In our function, L corresponds to the `size` parameter, so our code sets the height variable as follows:

```
height = size * math.sqrt(3) / 2
```

Geometry also tells us that the center of the triangle is one-third of the height from the bottom side and two-thirds of the height from the top point. This gives us the information we need to move the turtle to its starting position:

Python

```
def drawTriangleOutline(size, depth):  
    size = int(size)  
  
    # Move the turtle to the top of the equilateral triangle:
```
