

correct incorrectly scanned texts, and we continued with a phrase completion algorithm that can add words to input phrases to match the content and style of a text corpus. The approaches we took to these algorithms are similar to the approaches that work for other types of language algorithms, including spell checkers and intent parsers.

In the next chapter, we'll explore machine learning, a powerful and growing field that every good algorithm-smith should be familiar with. We'll focus on a machine learning algorithm called *decision trees*, which are simple, flexible, accurate, and interpretable models that can take you far on your journey through algorithms and life.
