

We continue to add entries to the doubling column by following the same rule: just double the previous entry. We do this until the doubling column has as many entries as the halving column ([Table 2-5](#)).

[Table 2-5:](#) *Halving/Doubling Table, Part 5*

Halving	Doubling
89	18
44	36
22	72
11	144
5	288
2	576
1	1,152

The next step is to cross out or remove every row in which the halving column contains an even number. The result is shown in [Table 2-6](#).

[Table 2-6:](#) *Halving/Doubling Table, Part 6*

Halving	Doubling
89	18
11	144
5	288
1	1,152

The final step is to take the sum of the remaining entries in the doubling column. The result is $18 + 144 + 288 + 1,152 = 1,602$. You can check with a calculator that this is correct: $89 \times 18 = 1,602$. We have accomplished multiplication through halving, doubling, and addition, all without needing to memorize most of the tedious multiplication table that young children so despise.

To see why this method works, try rewriting the doubling column in terms of 18, the number we are trying to multiply ([Table 2-7](#)).
