

magic square's *antidiagonal*, the bottom-left-to-top-right line shown in [Figure 2-3](#).

[Figure 2-3](#): The antidiagonal of a square matrix

You can see the cells that are on the antidiagonal. The antidiagonal line passes fully through them. We can follow our normal two rules when we are dealing with these cells. We need the exceptional third rule only when starting in a cell that is fully above the antidiagonal and crossing to a cell that is fully below it, or vice versa. That final rule is expressed in [Figure 2-4](#), which shows an antidiagonal and two cells that would need to follow this rule when crossing it.
