

Computer window coordinates work in a similar way ([Figure 5-2](#)).

*Figure 5-2: A computer window's coordinate system*

However, there are a few key differences:

1. The origin (0, 0) point is in the upper-left corner of the window.
2. The y-axis is reversed so that y values start at zero at the top of the window and increase as you go down.
3. The x and y values are always integers. Each (x, y) pair specifies a single pixel in the window. These values are always specified as relative to the upper-left corner of the window, not the screen. That way, the user can move the window anywhere on the screen without affecting the coordinates of the elements of the program displayed in the window.

The full computer screen has its own set of (x, y) coordinates for every pixel and uses the same type of coordinate system, but programs rarely, if ever, need to deal with screen coordinates.

When we write a pygame application, we need to specify the width and height of the window we want to create. Within the window, we can address any pixel using its x- and y-coordinates, as shown in [Figure 5-3](#).
