

The only change here is that we always draw the ball at the location given by the tuple `(ballX, ballY)` ⑦. The effect is that whenever the user clicks inside the rectangle of the ball, the ball appears to move to some new random spot in the window.

Handling the Keyboard

The next step is to allow the user to control some aspect of the program through the keyboard. There are two different ways to handle user keyboard interactions: as individual key presses, and when a user holds down a key to indicate that an action should happen for as long as that key is down (known as *continuous mode*).

Recognizing Individual Key Presses

Like the mouse clicks, each key press generates two events: key down and key up. The two events have different event types: `pygame.KEYDOWN` and `pygame.KEYUP`.

[Listing 5-4](#) shows a small sample program that allows the user to move the ball image in the window using the keyboard. The program also shows a target rectangle in the window. The user's goal is to move the ball image so that it overlaps with the target image.

File:

PygameDemo3_MoveByKeyboard/PygameMoveByKeyboardOncePerKey.py

```
# pygame demo 3(a) - one image, move by keyboard

# 1 - Import packages
import pygame
from pygame.locals import *
import sys
import random

# 2 - Define constants
BLACK = (0, 0, 0)
WINDOW_WIDTH = 640
WINDOW_HEIGHT = 480
```
