

Figure 7-2: A `TextButton` using defaults

You can override any or all of the default parameters with keyword values like so:

```
oButton = pygwidgets.TextButton(window, (50, 50), 'Text Button',
                                width=200,
                                height=30,
                                textColor=(255, 255, 128),
                                upColor=(128, 0, 0),
                                fontName='Courier',
                                fontSize=14,
                                soundOnClick='sounds/blip.wav',
                                enterToActivate=True)
```

This instantiation will create a button that looks like [Figure 7-3](#).

Figure 7-3: A `TextButton` using keyword arguments for font, size, colors, and so on

The image-switching behavior of these two buttons would work exactly the same way; the only differences would be in the appearance of the images.

CustomButtons

The `CustomButton` class allows you to use your own art for a button. To instantiate a `CustomButton`, you need only pass in a window, a location, and a path to the image of the up state of the button. Here is an example:

```
restartButton = pygwidgets.CustomButton(window, (100, 430),
                                       'images/RestartButtonUp.png')
```

The `down`, `over`, and `disabled` states are optional keyword arguments, and for any of these where no value is passed in, `CustomButton` will use a copy of the
