

At the bottom of the main `while` loop, you need to call the object's `draw()` method:

```
oTextField.draw()
```

And of course, you can create as many `DisplayText` objects as you wish, each displaying different text and each with its own font, size, color, and so on.

Text Input

In a typical text-based Python program, to get input from the user you would make a call to the `input()` function, which stops the program until the user enters text in the shell window. But in the world of event-driven GUI programs, the main loop never stops. Therefore, we must use a different approach.

For text input from the user, a GUI program typically presents a field that the user can type in. An input field must deal with all keyboard keys, some of which show while others are used for editing or cursor movement within the field. It must also allow for the user holding down a key to repeat it. The `pygwidgets InputText` class provides all this functionality.

The only required arguments to instantiate an `InputText` object are the window and a location:

```
oInputField = pygwidgets.InputText(window, (10, 100))
```

However, you can customize the text attributes of an `InputText` object by specifying optional keyword arguments:

```
oInputField = pygwidgets.InputText(window, (10, 400),
                                     value='Starting Text',
                                     fontName='Helvetica',
                                     fontSize=40,
                                     width=150,
                                     textColor=(255, 255, 0))
```

After instantiating an `InputText` field, the typical code in the main loop would look like this:
