

I demonstrated how Python creates a special variable called `__name__` and gives it different values depending on whether a file is being run as the main program or not. You can use this feature to add some test code that runs when you run the file as a main program (to test the code in the module), but will not run in the typical case when the file is imported by another module.

Finally, I showed how you can build different types of card decks, depending on how different they are from the `Deck` class.
