

I will get into all the details starting in the next chapter. While I am not expecting you to fully understand this example yet, notice that there is a combination of code and data in a single script (called a *class*). Here is your first look at object-oriented code.

File: Account.py

```
# Account class

class Account():
    def __init__(self, name, balance, password):
        self.name = name
        self.balance = int(balance)
        self.password = password

    def deposit(self, amountToDeposit, password):
        if password != self.password:
            print('Sorry, incorrect password')
            return None

        if amountToDeposit < 0:
            print('You cannot deposit a negative amount')
            return None

        self.balance = self.balance + amountToDeposit
        return self.balance

    def withdraw(self, amountToWithdraw, password):
        if password != self.password:
            print('Incorrect password for this account')
            return None

        if amountToWithdraw < 0:
            print('You cannot withdraw a negative amount')
            return None

        if amountToWithdraw > self.balance:
            print('You cannot withdraw more than you have in your account')
            return None

        self.balance = self.balance - amountToWithdraw
        return self.balance
```
