

```
oTV1.showInfo()  
oTV2.showInfo()
```

Listing 2-9: Creating two instances of the `TV` class and calling methods of each

If we run this code, it will generate the following output:

```
Status of TV:  
  TV is: On  
  Channel is: 2  
  Volume is: 7  
  
Status of TV:  
  TV is: On  
  Channel is: 44  
  Volume is: 10 (sound is muted)
```

Each `TV` object maintains its own set of the instance variables defined in the class. This way, each `TV` object's instance variables can be manipulated independently of those of any other `TV` object.

Initialization Parameters

The ability to pass arguments to method calls also works when instantiating an object. So far, when we've created our objects, we've always set their instance variables to constant values. However, you'll often want to create different instances with different starting values. For example, imagine we want to instantiate different TVs and identify them using their brand name and location. This way, we can differentiate between a Samsung television in the family room and a Sony television in the bedroom. Constant values would not work for us in this situation.

To initialize an object with different values, we add parameters to the definition of the `__init__()` method, like this:

```
# TV class  
  
class TV():  
    def __init__(self, brand, location): # pass in a brand and location for the  
    TV
```
